NEW THIAZOLIDINEDIONE, OXAZOLIDINEDIONE AND
OXADIAZOLIDINEDIONE DERIVATIVES

Field of invention

5

The present invention relates to certain novel thiazolidinedione, oxazolidinedione and oxadiazolidinedione derivatives, to a process for preparing such derivatives, having the utility in clinical conditions associated with insulin resistance, to methods for their therapeutic use and to pharmaceutical compositions containing them.

10

Background of the invention

15

Insulin resistance, defined as reduced sensitivity to the actions of insulin in the whole body or individual tissues such as skeletal muscle, myocardium, fat and liver prevail in many individuals with and without diabetes mellitus. The insulin resistance syndrome, IRS, refers to a cluster of manifestations including insulin resistance with accompanying hyperinsulinemia, possibly non insulin dependent diabetes mellitus (NIDDM); arterial hypertension; central (visceral) obesity; dyslipidemia observed as deranged lipoprotein levels typically characterized by elevated VLDL (very low density lipoproteins) and reduced HDL (high density lipoproteins) concentrations; and reduced fibrinolysis.

20

25

Recent epidemiological research has documented that individuals with insulin resistance run a greatly increased risk of cardiovascular morbidity and mortality, notably suffering from myocardial infarction and stroke. In non-insulin dependent diabetes mellitus these atherosclerosis related conditions cause up to 80% of all deaths.

In clinical medicine there is at present only limited awareness of the need to increase the insulin sensitivity in IRS and thus to correct the dyslipidemia which is considered to cause the accelerated progress of atherosclerosis.

30

Furthermore there is at present no pharmacotherapy available to adequately correct the metabolic derangements associated with IRS. To date, the treatment of NIDDM has been focused on correction of the deranged control of carbohydrate metabolism associated with the disease. Stimulation of endogenous insulin secretion by means of secretagogues, like sulphonylureas, and if necessary administration of exogenous insulin are methods frequently used to normalize blood sugar but that will, if anything, further enhance insulin resistance and will not correct the other manifestations of IRS nor reduce cardiovascular morbidity and mortality. In addition such treatment involves a significant risk of hypoglycemia with associated complications.

10

Other therapeutic strategies have focused on aberrations in glucose metabolism or absorption, including biguanides, such as methformin, or glucosidase inhibitors, such as acarbose. Although these agents have been efficacious to a degree, their limited clinical effect is associated with side effects.

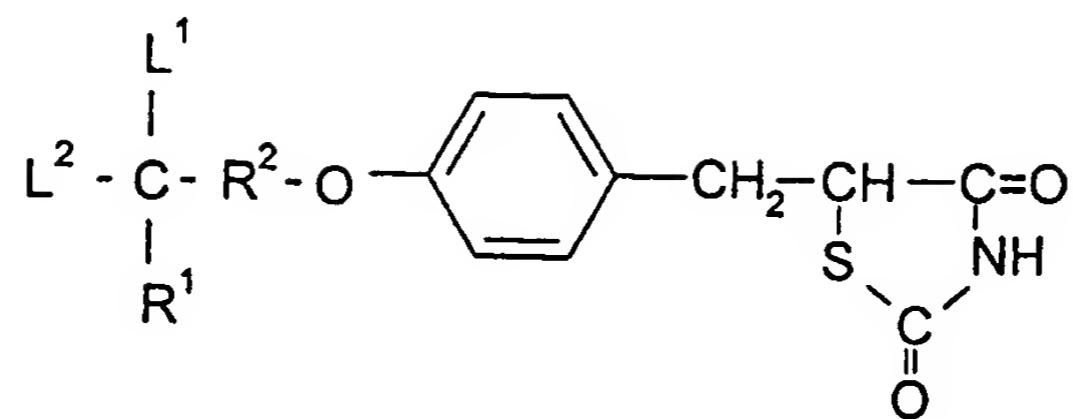

15

A novel therapeutic strategy involves the use of insulin sensitizing agents, such as the thiazolidinediones. Ciglitazone is the prototype in this class. In IRS these compounds seem to correct insulin resistance and the associated hypertriglyceridaemia and hyperinsulinemia, as well as hyperglycemia in diabetes, by improving insulin sensitivity via an effect on lipid transport and handling, leading to enhanced insulin action in skeletal muscle, liver and adipose tissue.

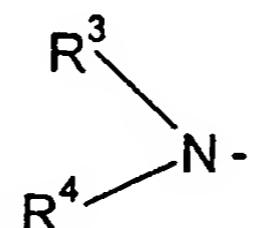

Ciglitazone as well as later described thiazolidinediones in clinical development either has been discontinued reportedly due to unacceptable toxicity or show inadequate potency. 25 Therefore there is a need for new and better compounds with insulin sensitizing properties.

Methods of preparation

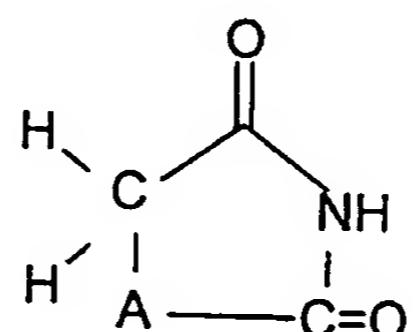

The compounds of the invention may be prepared as outlined below according to any of methods A-C. However, the invention is not limited to these methods, the compounds may 5 also be prepared as described for structurally related compounds in the prior art.

A. The compounds of the invention of formula I wherein A is S or O, B is C or CH can be prepared by a condensation reaction of a carbonyl compound of the formula II

10

with a compound of the formula

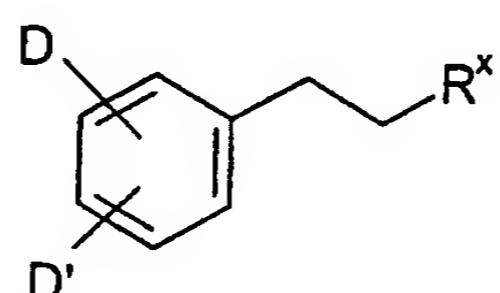

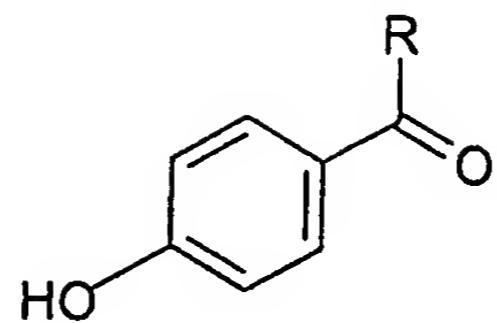

and if desired, followed by reduction of the obtained compound.

15

The compound of the formula II is prepared by coupling a compound of formula

20 with a compound of formula

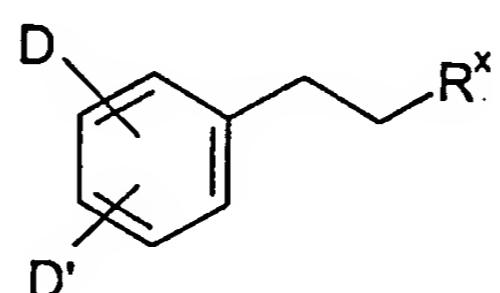

at, for example alkylation conditions or by a Mitzunobu reaction (Tsunoda, Tetr. Lett. 34, 1639-42 (1993), when necessary followed by modifications of the D-group as described in
5 the experimental section.

The group R^x can be a sulfonate, a halogen or an alcohol.

The compound of formula

10

can be prepared by standard procedures known to anyone skilled in the art, from commercial
15 available starting materials.

In the condensation step an approximately equimolar amounts of reactants are heated in the presence of a mild base, such as sodium acetate or piperidine acetate to provide the olefin compound of formula I wherein --- is a double bond. This step may be carried out in
20 the presence of a reaction inert solvent or in the absence of solvent at a temperature which is sufficiently high to cause at least partial melting of the reaction mixture. A preferred such temperature is in the range of 100°C to 250°C.

In a typical such reaction the aldehyde or ketone starting material and thiazolidinedione/
25 oxazolidinedione are combined in approximately equimolar amounts with molar excess,

pref. 1-4 fold molar excess, of anhydrous sodium acetate and the mixture is heated, at a temperature high enough to effect melting and if necessary under vacuum. The olefin (compound of formula I wherein --- is a double bond) can then be isolated by mixing with water or acetone and followed by filtration of the precipitate, to obtain the 5 crude product which is purified if desired, e.g. by recrystallization or by standard chromatographic methods.

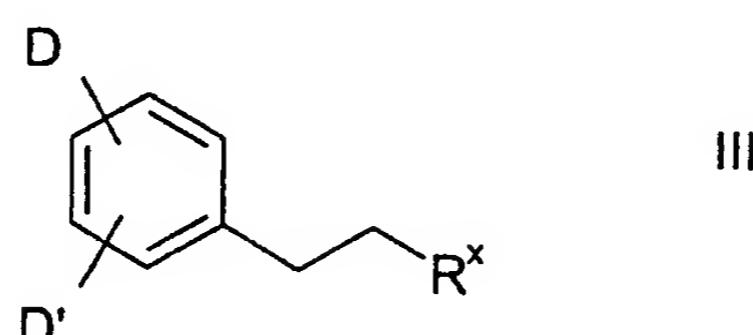

This reaction also takes place conveniently in a solvent such as toluene in presence of piperidine acetate. The resulting solution is refluxed with water separation in a Dean-Stark 10 apparatus. The solution is then cooled and the olefin product isolated and purified, by standard methods.

The reduction of the olefin may be carried out by employing a wide variety of reducing agents which are known to reduce carbon-carbon double bonds, such as catalytic 15 hydrogenation in the presence of an appropriate catalyst, magnesium or sodium amalgam in a lower alcohol such as methanol, or hydrogen transfer reagents such as diethyl-2,5-dimethyl-1,4-dihydropyridine-3,5-dicarboxylate.

The catalytic hydrogenation can be conducted in alcohol, cellosolves, protic polar organic 20 solvents, ethers, alkoxyalkanes, lower alifatic acids, and particularly methanol, ethanol, methoxyethanol, dimethylformamide, tetrahydrofuran, dioxane, dimethoxyethane, ethylacetate or acetic acid is preferably used alone or in mixture. Examples of the catalyst used include palladium black, palladium on carbon and platinum oxide. This reaction can proceed at normal temperature under normal pressure or at elevated temperature under 25 increased pressure depending on the reactivity of the aimed reaction.

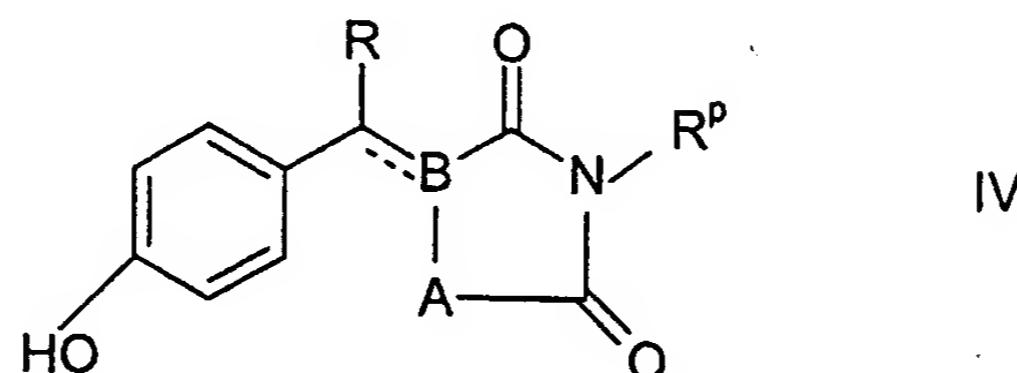

In case of hydrogen transfer reaction with diethyl-2,5-dimethyl-1,4-dihydropyridine-3,5-dicarboxylate the reaction is conducted by mixing equimolar amounts of reactants and warming the mixture to melting (140-250°C) under inert atmosphere or under vacuum.

B. The compounds of the invention of formula I can be prepared by reaction of a compound of the formula

5

with a compound of the formula

10 wherein D, D', R, A and B are as defined above, Rx is a leaving group or a -OH group and Rp is hydrogen or a protecting group, either by an alkylation reaction or a Mitsunobu reaction, when necessary followed by deprotection of the protective group Rp.

15 In an alkylation reaction the leaving group Rx can be a sulfonate such as mesylate, nosylate, tosylate, or a halogen, such as bromine or iodine. The compounds of formula III and IV in approximately eqimolar amounts or with an excess of either compound are heated to reflux temperature in an inert solvent, such as isopropanol or acetonitrile, in the presence of a base, such as potassium carbonate or cesium carbonate.

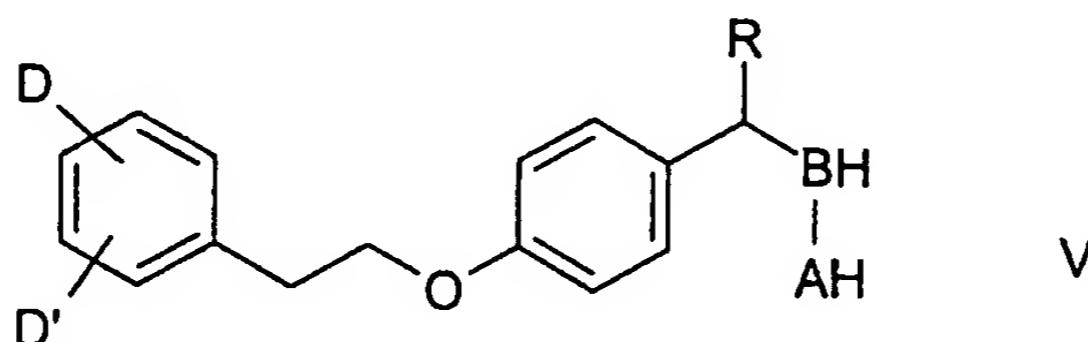

20 The mixture is refluxed for the necessary time, typically between 0.5 h to 24 h, the work up procedure usually include filtration, for removal of solid salt, evaporation and extraction with water and an organic solvent such as dichloromethane, ethylacetate, or diethyl ether. The crude product is purified if desired e.g. by recrystallization or by standard chromatographic methods.

The Mitzunobu reaction can be carried out according to standard methods.

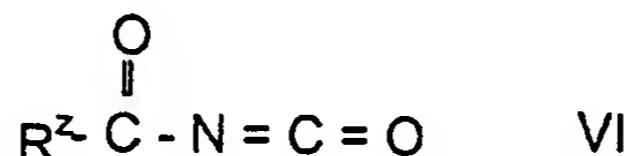

In a typical Mitzunobu reaction a compound of formula III, wherein the group R^X is a hydroxyl group, and a compound of formula IV are mixed in an inert solvent, such as 5 chloroform or dichloromethane, in approximately equimolar amounts. A slight molar excess, 1-4 equivalents, of azodicarboxylate, such as DEAD (diethyl azodicarboxylate) or ADDP (azodicarbonyl dipiperidine) and a phosphine (1-4 equivalents), such as tributylphosphine or triphenylphosphine are added and the reaction is stirred at a 10 temperature high enough - for example room temperature - and a time long enough (1-24 hours) to obtain the crude product, which can be worked up with standard litterature methods and if desired purified, e.g. by standard chromatographic methods.

C. The compounds of the invention of the formula I wherein A is O, B is N, and --- is a single bond can be prepared by reaction of a compound of the formula

15

20 with a compound of the formula VI

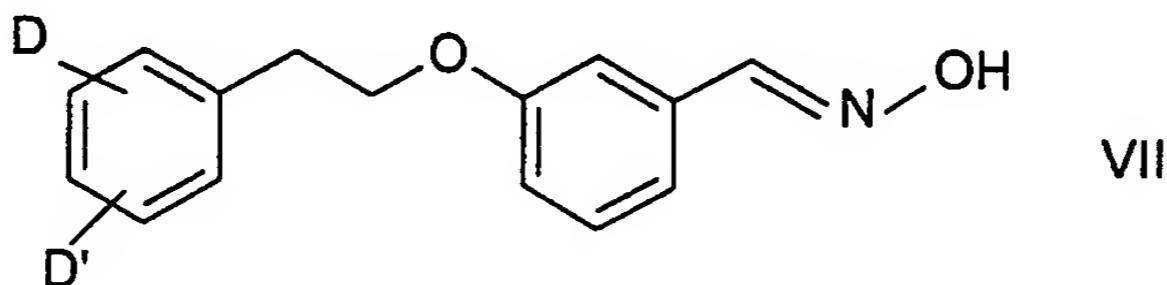

25 wherein D, D', R, A and B are as defined above and R^z is a halogen, preferably chlorine.

In a typical reaction the compound of formula VI is added to a cool solution of a compound of formula V in an inert solvent, such as tetrahydrofuran or diethylether, preferentially at a slow enough speed to keep the temperature below -5°C. The reaction mixture is stirred at a temperature between -10°C and room temperature for an appropriate time.

The reaction can be worked up by acidification, e.g. by pouring it onto a water solution of hydrochloric acid, and extraction with the aid of an organic solvent. The crude product of the desired compound can be purified if desired by crystallization or standard chromatographic methods.

The compounds of formula V can be prepared by reduction of a compound of formula VII

15

in a solvent such as tetrahydofuran and/or methanol, using an excess of a reducing agent, such as sodium cyanoborohydride.

20

In a typical such reaction an excess of the reducing agent, e.g. sodium cyanoborohydride, is added to a solution of a compound of formula VII in methanol and tetrahydofuran.

Hydrochloric acid in a solvent, such as dioxan can be added.

25

The reaction can be worked up according to literature and if necessary purified by standard chromatographic methods to give the compound of formula V.

The compound of formula VII can be prepared by reacting a compound of formula II with hydroxyl amine.

A typical such reaction is performed by adding an excess of hydroxyl amine hydrochloride and a base, such as sodium acetate in water, to a solution of a compound of formula II in a solvent, such as ethanol. The reaction can be performed at a temperature of 50°C for 1.5 hours.

The crude product can be purified by crystallization to give the compound of formula VII.

10

The compound of formula II can be prepared as described in method A.

5 Biological activity

The biological activity of the compounds was tested in obese diabetic mice of the Umeå ob/ob strain. Groups of mice received the test compound by gavage once daily for 7 days. On the last day of the experiment the animals were anesthetized 2h after dose in a non-fed 10 state and blood was collected from an incised artery. Plasma was analyzed for concentration of glucose, insulin and triglycerides. A group of untreated obese diabetic mice of the same age served as control. The individual values for glucose, insulin and triglyceride levels of the mice from the test group were expressed as the percent rage of the corresponding values from the control group.

15 The desired "therapeutic effect" was calculated as the average percent reduction of the three variables glucose, insulin and triglycerides below the levels in the control animals. The therapeutic effect of the tested compounds according to the invention was compared to the same effect in the prior art compound troglitazone, administrered by gavage in the oral dose of 300 μmol/kg for 7 days.

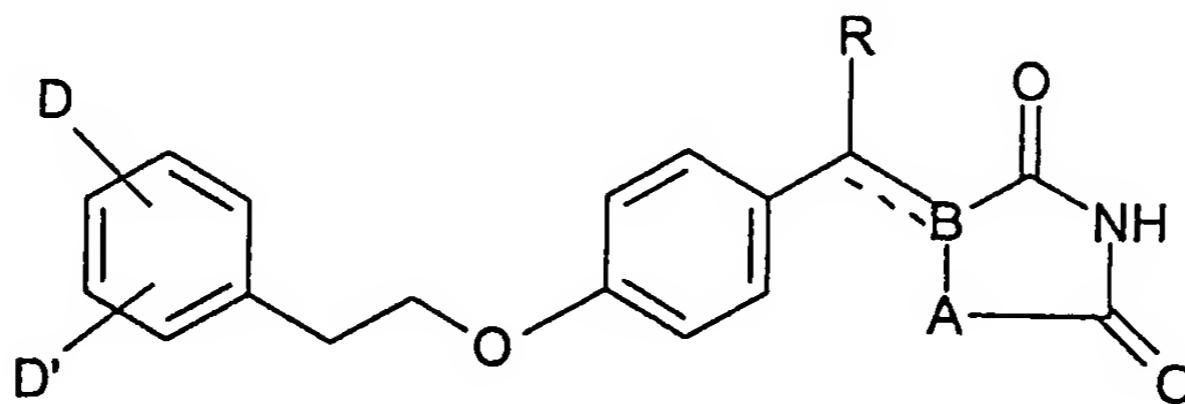

20

The superior effects of the tested compounds according to the invention compared to that of troglitazone when given in the same oral dose demonstrate the increased potency and efficacy of the claimed compounds.

PCT/SE 98/01066

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.: 14
because they relate to subject matter not required to be searched by this Authority, namely:
Claim 14 relates to a method of treatment of the human or animal body by surgery or by therapy. See PCT, Rule 39.1 (iv). Nevertheless, a search has been executed for this claim. The search has been based on the alleged effects of the compounds/compositions.
2. Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

The additional search fees were accompanied by the applicant's protest.

No protest accompanied the payment of additional search fees.
